## Arrays in C/C++

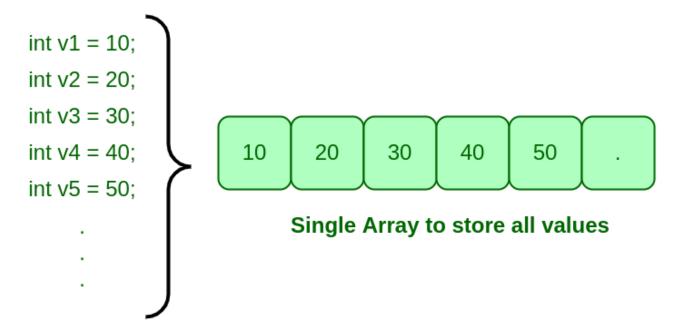

- 1. It is a group of variables of similar data types referred to by a single element.
- 2. Its elements are stored in a contiguous memory location.
- 3. The size of the array should be mentioned while declaring it.
- 4. Array elements are always counted from zero (0) onward.
- 5. Array elements can be accessed using the position of the element in the array.
- 6. The array can have one or more dimensions.

An array in C/C++ or be it in any programming language is a collection of similar data items stored at contiguous memory locations and elements can be accessed randomly using indices of an array.

## Why do we need arrays?

We can use normal variables (v1, v2, v3, ...) when we have a small number of objects, but if we want to store a large number of instances, it becomes difficult to manage them with normal variables. The idea of an array is to represent many instances in one variable.

# Multiple variables to store each value

#### Advantages:-

- Code Optimization: we can retrieve or sort the data efficiently.
- Random access: We can get any data located at an index position.

#### Disadvantages:-

• Size Limit: We can store only the fixed size of elements in the array. It doesn't grow its size at runtime.

An array is a variable that can store multiple values. For example, if you want to store 100 integers, you can create an array for it.

```
int data[100];
```

## How to declare an array?

```
dataType arrayName[arraySize];
For example,
    float mark[5];
```

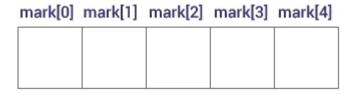

Here, we declared an array, mark, of floating-point type. And its size is 5. Meaning, it can hold 5 floating-point values.

It's important to note that the size and type of an array cannot be changed once it is declared.

## **Access Array Elements**

You can access elements of an array by indices.

Suppose you declared an array mark as above. The first element is mark[0], the second element is mark[1] and so on.

#### Few keynotes:

- Arrays have 0 as the first index, not 1. In this example, **mark[0]** is the first element.
- If the size of an array is **n**, to access the last element, the **n-1** index is used. In this example, **mark[4]**

## How to initialize an array?

It is possible to initialize an array during declaration. For example,

```
int mark[5] = {19, 10, 8, 17, 9};
```

You can also initialize an array like this.

```
int mark[] = {19, 10, 8, 17, 9};
```

Here, we haven't specified the size. However, the compiler knows its size is 5 as we are initializing it with 5 elements.

mark[0]	mark[1]	mark[2]	mark[3]	mark[4]
19	10	8	17	9

Here,

```
mark[0] is equal to 19
mark[1] is equal to 10
mark[2] is equal to 8
mark[3] is equal to 17
mark[4] is equal to 9
Change Value of Array elements
int mark[5] = \{19, 10, 8, 17, 9\}
// make the value of the third element to -1
mark[2] = -1;
// make the value of the fifth element to 0
mark[4] = 0;
Example 1 | Array Input/Output
// Print the elements stored in the array
#include <stdio.h>
int main() {
 int values[5];
```

```
// Program to take 5 values from the user and store them in an array
// Print the elements stored in the array
#include <stdio.h>
int main() {
  int values[5];
  printf("Enter 5 integers: ");
  // taking input and storing it in an array
  for(int i = 0; i < 5; ++i) {
    scanf("%d", &values[i]);
  }
  printf("Displaying integers:\n");

// printing elements of an array
  for(int i = 0; i < 5; ++i) {
    printf("%d ", values[i]);
  }
  return 0;
}</pre>
```

#### Output

```
Enter 5 integers: 7 2 9 1 8
Displaying integers:
7 2 9 1 8
```

### **Example 2 | Calculate Sum**

```
// Program to find the sum of 5 numbers using arrays
#include <stdio.h>
int main() {
  int marks[5], i, n, sum = 0;
  for(i=0; i < 5; ++i) {
    printf("Enter number%d: ",i+1);
    scanf("%d", &marks[i]);

    // adding integers entered by the user to the sum variable
    sum += marks[i];
}
printf("Sum = %d", sum);
return 0;
}</pre>
```

#### Output

```
Enter number1: 3
Enter number2: 5
Enter number3: 1
Enter number4: 2
Enter number5: 8
Sum = 19
```
